## ACKNOWLEDGMENTS

The following staff of the New Jersey State Cancer Registry and the Cancer Research Program of the Cancer Epidemiology Services, the Cancer Surveillance Unit of the Consumer, Environmental and Occupational Health Services and the Rutgers Cancer Institute of New Jersey were involved in the collection, quality assurance and preparation of the data on incident cases of cancer in New Jersey:

|                         |                               |

## INTRODUCTION

This report presents statewide, age-adjusted incidence rates and counts for all cancers diagnosed among New Jersey residents during the period 2008-2012.

The primary goal of this report is to provide 2008-2012 cancer statistics to healthcare planners, researchers and the public. Statistics are presented statewide for eight population subgroups: white men, white women, black men, black women, Hispanic men, Hispanic women, Asian and Pacific Islander men, and Asian and Pacific Islander women. These statistics are also presented by gender for all races combined. Statistics are presented by stage at diagnosis for selected cancer sites by gender and race/ethnicity.

The age-adjusted incidence and mortality rates per 100,000 population are presented by major cancer sites and for all sites combined by year of diagnosis. Asian and Pacific Islander data are presented for the combined five-year period of 2008-2012. For the incidence counts and rates, *in situ* cancers are not included except for bladder cancer *in situ* cases, which are included with invasive urinary bladder, urinary system and all sites. Breast cancer *in situ* cases for women are shown but not included in the totals for all sites combined. Basal and squamous cell skin cancers are not collected and therefore not included in the tables. Benign and borderline brain tumor incidence data for 2008-2012 are presented separately. Myelodysplastic syndromes (MDS) and chronic myeloproliferative disorders (CMD) are defined as malignant starting in 2001 with ICD-O-3 and are included in “All Sites” and in the “Ill Defined” category in the rate tables. MDS and CMD incidence rates are presented separately. These conventions are standard practice for publication of cancer rates in the United States.

Additional New Jersey cancer incidence, mortality, survival, and prevalence data are available from the Cancer Epidemiology Services office or on our website, <http://nj.gov/health/ces/index.shtml>, including:

- *Cancer Survival in New Jersey, 1979-2005;*
- *Cancer Prevalence in New Jersey, 1/1/2009;*
- *Cancers with Population-Based Screening Methods – Incidence, Stage at Diagnosis, and Screening Prevalence, New Jersey;*
- *Cancer Among Asians and Pacific Islanders in New Jersey, 1990-2007;*
- *Adolescent and Young Adult Cancer in New Jersey - 1979-2006;*
- *Childhood Cancer in New Jersey, 1979-2005;* and
- *Area Socioeconomic Variations in Cancer Incidence and Stage at Diagnosis in New Jersey, 1996-2002.*

Our interactive cancer statistics mapping application provides incidence and mortality counts and rates statewide and at the county level by year, age, sex, race, and ethnicity for the years 1990 and later at <http://nj.gov/health/ces/cancer-rates.shtml>. ## SUMMARY

### **Cancer Incidence, New Jersey 2008-2012**

A total of 48,481 cases of invasive cancer diagnosed in 2012 among New Jersey residents were reported to the New Jersey State Cancer Registry (NJSCR), which is slightly lower compared to 49,004 reported cases diagnosed in 2011. During the period 2008-2012, a total of 244,532 cases of invasive cancer were diagnosed among New Jersey residents, 50.2% among men and 49.8% among women, 83.8% among whites, 11.1% among blacks, and 3.5% among Asians and Pacific Islanders (API). Hispanics of any race accounted for 8.3% of the total cancer cases.

Primary cancers with the ten highest age-adjusted incidence rates during 2008-2012 in New Jersey were prostate, lung, colon and rectum, urinary bladder, melanoma of the skin, non-Hodgkin lymphoma, kidney and renal pelvis, leukemia, pancreas and oral cavity and pharynx for men; and breast, lung, colon and rectum, endometrial (corpus and uterus, NOS), thyroid, non-Hodgkin lymphoma, melanoma of the skin, ovary, pancreas, and urinary bladder for women. These accounted for 79% of all incident cancers (Tables 1 and 2).

In New Jersey, the average age-adjusted total cancer incidence rate for men was 564.0 per 100,000 for the years 2008-2012 combined, with decreasing rates since 2008 (Table 1). Lung and colorectal cancer incidence rates among all men continued to decrease during this time period (Table 1). New Jersey prostate cancer incidence rates decreased by approximately 20% from 2011 to 2012. A similar decrease in prostate cancer incidence was observed in other U.S. states in 2012 (Howlander et al., 2015). Thyroid cancer incidence rates continued to increase for all men, especially among white men each year from 2008 to 2012. Thyroid cancer rates for white men were more than double the rates for black men, 10.3 per 100,000 versus 4.1, respectively (Tables 3 and 5). Total cancer incidence rates declined during 2008-2012 for white men and decreased for black men after 2009. Total cancer incidence rates were higher in black men than white men before 2011, while rates were higher in white men during 2011 and 2012. This convergence is fueled by decreasing trends in prostate, lung, colorectal, and laryngeal cancer incidence rates (Tables 3 and 5). Black men still had higher prostate cancer, lung cancer, and multiple myeloma incidence rates and lower bladder cancer, melanoma, and non-Hodgkin lymphoma incidence rates compared to white men (Tables 3 and 5).

The age-adjusted total cancer incidence rates for all New Jersey women remained fairly stable, with a slight decrease after 2009. The average annual incidence rate for New Jersey women was 449.9 per 100,000 women during 2008-2012. Incidence rates for some of the most common cancers, including breast and endometrial, remained stable while decreasing rates were noted for lung, colorectal and cervical cancers among women (Table 2). The total cancer incidence rate, as well as rates of lung, breast, and endometrial cancers and melanoma, for black women continued to be lower compared to white women (Tables 4 and 6). However, black women had higher incidence rates for most digestive system cancers, cervical cancer, and myelomas compared to white women. Thyroid cancer incidence rates increased for all women through 2009. The thyroid cancer rates for white women were more than double the rates for black women, 31.0 per 100,000 versus 12.1, respectively (Tables 4 and 6).

New Jersey Hispanics continued to have lower incidence rates for all cancers combined and for many of the most common types of cancer in the general population, including lung, female

breast, prostate, bladder, and melanoma of the skin (Tables 7 and 8). But Hispanics continued to have higher incidence rates for stomach, liver, and cervical cancers compared with the general population in New Jersey. Among Hispanic men and women, thyroid cancer incidence rates followed an increasing trend similar to New Jersey as a whole (Tables 7 and 8).

New Jersey Asians and Pacific Islanders continue to have much lower cancer incidence rates compared to the general population for all cancers combined and most common types of cancer such as lung, colorectal, female breast and prostate. Stomach, liver and nasopharyngeal cancer incidence rates were higher for Asians and Pacific Islanders than in the general population (Table 9).

A review of the incidence of benign and borderline brain and central nervous system tumors in New Jersey showed that these tumors occurred mostly in intracranial meninges and the sellar region, while invasive brain tumors occurred mostly in the brain proper. This pattern was similar to the results seen in U.S. SEER data (Howlader et al., 2015). New Jersey incidence data for 2008-2012 showed women had higher rates compared to men for these types of tumors and rates were fairly similar among whites and blacks. Women also had higher benign intracranial meningioma incidence rates compared to men during this same time period (Table 10).

A review of myelodysplastic syndromes (MDS) and chronic myeloproliferative disorders (CMD), which are precursors related to hematologic cancers, showed that they occurred more frequently among men than women in New Jersey. The age-adjusted incidence rate for MDS and CMD combined during 2008-2012 was 10.9 per 100,000 in men and 6.5 per 100,000 in women. White men had higher incidence of MDS compared to any other racial group/ethnicity (Table 11).

Cancers diagnosed at an early stage (*in situ* and local) have better treatment outcomes and better survival. For screenable cancers among New Jersey men diagnosed during 2008-2012, 89% of melanomas of the skin, 83% of prostate cancers, 41% of colorectal cancers and 17% of lung cancers were diagnosed at an early stage (Table 12). Among New Jersey women during this same time period, 91% of melanomas of the skin, 71% of breast cancers, 43% of cervical cancers, 40% of colorectal cancers and 21% of lung cancers were diagnosed at an early stage (Table 13). Black men had lower percentages of early-stage diagnoses compared to white men for all cancer sites presented. Black women had lower percentages of early-stage diagnoses for breast, cervical, and lung cancers but a higher percentage of early-stage diagnoses for colorectal cancer compared to white women. API men had a lower percentage of early-stage diagnoses for prostate cancer compared to other men. API women had lower percentages of early-stage diagnoses for colorectal cancer and melanoma compared to the other groups. Hispanic men had a lower percentage of early-stage diagnoses for melanoma compared to the New Jersey male population and a higher percentage of early-stage diagnoses for prostate cancer. Hispanic women had lower percentages of early-stage diagnoses for breast cancer and melanoma but higher percentages of early-stage diagnoses for cervical and colorectal cancers compared to the general female population (Tables 12 and 13).

## **Cancer Incidence in New Jersey and U.S. 2008-2012**

Comparing New Jersey and U.S. age-adjusted incidence rates using data published in *Cancer in North America* by the North American Association of Central Cancer Registries (NAACCR) for 2008-2012, New Jersey incidence rates for all cancers combined continued to be higher than the U.S. rates, except for rates among black and API men and API women (Tables 14 and 15). Both New Jersey men and women had higher incidence rates compared to the U.S. for the most common cancers with some exceptions. New Jersey lung cancer incidence rates for men and women of all races combined, as well as white, black and API men and black and API women, were lower than the corresponding U.S. rates. New Jersey colorectal cancer incidence rates for black and API men and API women were lower than the U.S. rates, while rates for New Jersey black women were similar to the corresponding U.S. rates. New Jersey female breast cancer incidence rates were lower than the U.S. rates for black and API women, as well as New Jersey thyroid cancer incidence rates for black women. New Jersey melanoma incidence rates for black men and API women were lower than the U.S. rates, while New Jersey black and Hispanic women and Hispanic men had melanoma rates similar to the U.S. rates. New Jersey API men and women also had lower bladder cancer and non-Hodgkin lymphoma incidence rates compared to the U.S. rates, as well as lower rates of endometrial cancer (females). (Tables 14 and 15).

## **Cancer Mortality, New Jersey 2008-2012**

Among New Jersey residents, a total of 16,483 deaths occurred in 2012 for which cancer was designated on the death certificate as the underlying cause, a slight decline compared to 16,708 reported cancer deaths in 2011. During the five-year time period 2008-2012, a total of 83,420 cancer deaths occurred among New Jersey residents, 49.3% among men and 50.7% among women. Primary cancers with the highest age-adjusted mortality rates for 2008-2012 in New Jersey were lung, prostate, and colon and rectum for men; and lung, breast, and colon and rectum for women. These cancers accounted for 45.7% and 49.3% of the total cancer deaths for men and women, respectively. Overall age-adjusted cancer mortality rates for men and women in New Jersey continued to decline (Table 16 and 17), reflecting the trends seen in U.S. mortality data (Howlander et al., 2015).

New Jersey cancer mortality rates continued to be higher for men than for women during 2008-2012 (199.0 per 100,000 versus 147.4 per 100,000). This pattern was observed among all races and ethnicity groups. Cancer mortality rates, including all sites, colorectal, prostate, and female breast, for both black men and women continued to be higher compared to white men and women with a few exceptions. Black men also had higher lung cancer mortality rates but lower lymphoma, leukemia, melanoma, bladder and brain cancer mortality rates compared to white men. Black women had lower lymphoma, leukemia, lung and brain cancer mortality rates than white women (Tables 18-21). Overall cancer mortality rates, as well as mortality rates for many common cancers, for New Jersey Hispanic men and women were lower than rates for all New Jersey men and women, except for slightly higher mortality rates for liver, stomach and cervical cancer (Table 22). New Jersey Asians and Pacific Islanders had much lower total cancer mortality rates than for the New Jersey total population, as well as lower female breast, colorectal, lung, and prostate cancer rates. However, stomach cancer mortality rates for API women were higher than in the New Jersey female general population (Table 23).

### **Cancer Mortality in New Jersey and U.S. 2008-2012**

Comparing New Jersey and U.S. age-adjusted mortality rates for men during 2008-2012, New Jersey cancer mortality rates for all cancers, lung, and prostate cancer were lower than the corresponding rates for the U.S. for all men and in each racial/ethnic group, with the exception of prostate cancer mortality rates for New Jersey black men. New Jersey colorectal cancer mortality rates for all men, white men, and black men were slightly higher compared to the U.S. rates. Among all New Jersey women during the same time period, the cancer mortality rates for all cancers, breast and colorectal cancers were higher compared to the U.S. mortality rates. New Jersey total cancer mortality rates were higher than the corresponding U.S. rates for white women, but lower for black, API, and Hispanic women. New Jersey women had lower lung cancer mortality rates than U.S. women, and this pattern was observed for women of all racial/ethnic groups. The breast cancer mortality rate for New Jersey white women was higher than the U.S. rate, while New Jersey API and Hispanic women had lower breast cancer mortality rates. New Jersey colorectal cancer mortality rates were higher for white women than the corresponding U.S. rates, but lower for API and Hispanic women. New Jersey black women had colorectal cancer mortality rates similar to U.S. black women (Tables 24 and 25).

## TECHNICAL NOTES

### New Jersey State Cancer Registry (NJSCR)

#### NJSCR Overview

The objectives of the NJSCR are to:

- Monitor cancer trends in New Jersey
- Promote scientific research
- Educate the public
- Provide information for planning and evaluating cancer prevention and control activities
- Share and compare cancer data with other states and the nation
- Participate in population-based investigations of cancer etiology, prevention, treatment and outcomes

The NJSCR is a population-based cancer incidence registry that serves the entire state of New Jersey, which has a current estimated population of over 8.9 million people (U.S. Census Bureau). The NJSCR was established by legislation (N.J.S.A. 26:2-104 et seq.) and includes all cases of cancer diagnosed in New Jersey residents since October 1, 1978. New Jersey regulations (N.J.A.C. 8:57A) require the reporting of all newly diagnosed cancer cases to the NJSCR within three months of hospital discharge or six months of diagnosis, whichever is sooner. Reports are filed by hospitals, diagnosing physicians, dentists, and independent clinical laboratories. Every hospital in New Jersey reports cancer cases electronically. In addition, the NJSCR maintains reporting agreements with New York, Pennsylvania, and other surrounding states, as well as other state cancer registries that are enrolled in the North American Association of Central Cancer Registries (NAACCR) interstate data exchange program so that New Jersey residents diagnosed with cancer outside the state can be identified. Legislation passed in 1996 strengthened the NJSCR by requiring electronic reporting, requiring abstracting by certified tumor registrars, and establishing penalties for late or incomplete reporting.

All primary invasive and *in situ* neoplasms are reportable to the NJSCR, except cervical cancer *in situ* diagnosed after 1994 and certain carcinomas of the skin. Benign and borderline brain tumors diagnosed on or after January 1, 2004 are reportable according to Public Law 107-260, the Benign Brain Tumor Cancer Registries Act, which was signed in October 2002. The information collected by the NJSCR includes basic patient identifiers, demographic characteristics of the patient, medical information on each cancer diagnosis (such as the anatomic site, histologic type and stage of disease), first course of treatment and vital status (alive or deceased) annually. For deceased cases, the underlying cause of death is also included. The primary site, behavior, grade, and histology of each cancer are coded according to the *International Classification of Diseases for Oncology (ICD-O)*, 3<sup>rd</sup> edition for cancers diagnosed after 2000. The NJSCR follows the data standards promulgated by the NAACCR, including the use of the Surveillance, Epidemiology, and End Results (SEER) multiple primary rules. An individual may develop more than one cancer. Following the SEER multiple primary rules, patients could therefore be counted more than once if they were diagnosed with two or more primary cancers.

The NJSCR is a member of the NAACCR, an organization that sets standards for cancer registries, facilitates data exchange, and publishes cancer data. The NJSCR has been a participant of the National Program of Cancer Registries (NPCR) sponsored by the Centers for Disease Control and Prevention (CDC) since it began in 1994 and is a member of the National Cancer Institute's (NCI) SEER Program.

### **NJSCR Data Quality**

NAACCR has awarded the Gold Standard, the highest standard possible, to the NJSCR for the quality of the data for each diagnosis year 1995 through 2010 and 2012 and the Silver Standard for the 2011 diagnosis year. The NJSCR has consistently achieved the highest level of certification for its data since the inception of this award. The criteria used to judge the quality of the data are completeness of cancer case ascertainment, completeness of certain information on the cancer cases, percent of death certificate-only cases, percent of duplicate cases, passing an editing program, and timeliness.

Completeness of reporting to the NJSCR was estimated by comparing New Jersey and U.S. incidence to mortality rate ratios for whites and blacks, standardized for age, gender, and cancer site. The data used to generate these ratios were the cancer incidence rates for all SEER registries combined. Using these standard formulas, it is possible for the estimation of completeness to be greater than 100 percent. For 2012 data, the completeness of case reporting was estimated as 105 percent at the time this report was prepared.

While our estimates of completeness are very high, some cases of cancer among New Jersey residents who were diagnosed and/or treated in out-of-state facilities may not yet have been reported to the NJSCR by other state registries. This should be considered in interpreting the data for the more recent years. However, these relatively few cases will not significantly affect the overall trends over the time period presented in this report. The most recent year of data, in this case 2012, may be considered preliminary.

Other 2012 cancer incidence data quality indicators measured as follows:

- percent death-certificate-only cases: 1.6%
- percent of unresolved duplicates: < 0.1%
- percent of cases with unknown race: 1.3%
- percent of cases with unknown county: 0.03%
- number of cases with unknown age: 4
- number of cases with unknown gender: 8

It should also be noted that there may be minor differences in the New Jersey incidence and mortality rates in this report compared to previous reports, due to delayed reporting, ongoing editing and reviewing of the data. We also included myelodysplastic syndrome (MDS) and chronic myeloproliferative disorder (CMD) malignancies in the "All Sites" and "Ill-Defined & Unspecified Sites" categories, which made these rates higher than in reports published in 2012 or earlier, which did not include cases of MDS or CMD. Changes in the estimated population denominators also affect the incidence rates in this report and on our cancer mapping website compared to the previous years' publication.

The NJSCR continues to work toward improving the timeliness, quality, and number of its reporting sources. The NJSCR offers electronic reporting options for ambulatory care providers, such as: physician offices, radiation therapy centers, and freestanding surgery centers. In the past few years, the NJSCR has participated in two quality improvement projects to increase provider reporting. A targeted outreach to dermatologists and dermatology groups enhanced reporting of melanoma and other skin cancers. Reporting by independent radiation therapy centers improved the number of prostate and urological malignancy reports from urology specialists and radiation oncologists.

NJSCR has also made significant headway in identifying incident cases in a timely manner by increasing the number of facilities that use electronic pathology laboratory case identification. Currently, several hospital-based laboratories use the Artificial Intelligence in Medicine (AIM) electronic reporting software (E-Path) to automate cancer case identification for hospital tumor registry programs. NJSCR also uses E-Path to identify cancer reports from national pathology laboratories. One significant use of E-Path by a national laboratory ultimately increased the identification of hematological malignancies for the reporting period. The ultimate goal is to enable electronic pathology laboratory reporting from every laboratory that serves New Jersey, because it is evident that electronic pathology cancer identification has improved the timeliness and completeness of cancer reporting, especially for non-hospitalized case reports. Trends in future reporting are driving the NJSCR to develop appropriate systems to identify and receive HL7 messages, as well as to accept Meaningful Use data upon the implementation phase for cancer reporting.

One limitation that could affect New Jersey cancer incidence data is the federal formal restrictions on the submission of cancer cases from Veterans Health Administration (VA) hospitals to cancer registries. NJSCR received 0.6% of the total cases exclusively from VA hospitals for the years 2004 and earlier. Since then, the NJSCR received only 0.3% of the total cases from VA hospitals for 2005 and no cases for 2006 through 2012. The impact of missing VA hospital cases in New Jersey could result in underestimates of cancer incidence rates for men in 2008 through 2012. NJSCR is exploring the possibility of receiving electronic VA cases through a secure file transfer source.

## **Data Sources and Specifications**

### **Incidence Data**

New Jersey cancer incidence data were taken from the January 2015 analytic file of the NJSCR. All the counts and rates were tabulated using SEER\*Stat Version 8.1.5 (<http://www.seer.cancer.gov/seerstat/>), a statistical software package distributed by the NCI. U.S. cancer incidence data were obtained from NAACCR's publication, *Cancer in North America 2008-2012* (<http://www.naacr.org/DataandPublications/CINAPubs.aspx>).

The cancer categories in this report are based on the primary site and histology data fields as abstracted from the medical records. For detailed definitions of the cancer categories, please visit the SEER program website ([http://www.seer.cancer.gov/siterecode/icdo3\\_d01272003/](http://www.seer.cancer.gov/siterecode/icdo3_d01272003/)). We used the cancer site recode with mesothelioma and Kaposi sarcoma in separate categories in all incidence tables except for the benign and borderline brain tumor table.

Benign and borderline brain tumors are classified into six groups by primary site: brain, intracranial meninges, cranial nerves and other central nervous system, tumor of the sellar region (pituitary gland, craniopharyngeal duct, and pineal gland), spinal cord, and spinal meninges.

The coding scheme for incident cancer cases in this report is derived from *International Classification of Diseases for Oncology, 3<sup>rd</sup> edition (ICD-O-3)*. Cases included in the rate tables are all invasive cancers in ICD-O-3 except the benign and borderline brain tumor table. There are some reportability changes from ICD-O-2 to ICD-O-3 beginning in 2001. Myelodysplastic syndrome (MDS) (9980, 9982-9987, 9989) and chronic myeloproliferative disorder (CMD) (9950, 9960-9962) were defined as malignant in ICD-O-3. In previous reports published before 2013, we had only included cases that were reportable in ICD-O-2 and ICD-O-3 to ensure the comparability of rates. Because these cancers were reportable for the entire time period covered by this report, MDS and CMD are included in the rate tables for “All Sites” and in “Ill-Defined & Unspecified Sites” categories. The “All Sites” rates are higher than in the previous report tables published before 2013 because of the inclusion of these additional types of cancer.

Caution must be used when looking at statistics over time for total cancers or categories that include tumors with revised behavior. In this report, data presented for the most recent five years, 2008-2012, include cancers classified as malignant based on ICD-O-3, which is the current standard. However, for any time trends where incidence rates are displayed by year from 1979 to 2012, the practice followed by the National Cancer Institute should be used, excluding most newly-reportable cancers as well as the tumors that are no longer classified as malignant, for consistency purposes. The SEER program provides more detailed explanations (see <http://www.seer.cancer.gov/behavrecode/>).

### **Exclusions**

For this report, cases where the county of residence is unknown were excluded from the New Jersey rates and counts, in accordance with standard procedures used by SEER, and has been determined to have little effect on the incidence rates. For example, the total number of cases with unknown county for 2008-2012 is 232, representing 0.1% of the total cancer cases. The small numbers of cases with unknown age or gender were also excluded from the analyses. Since the number of records affected was very small, the rates were virtually unaffected by the exclusion of these records. Race-specific information is not shown separately for persons who are races other than white, black, or Asian and Pacific Islander, but these persons and persons of unknown race are included in the “all races” data.

### **Mortality Data**

New Jersey and U.S. cancer mortality data for 2008-2012 were obtained through the NCI SEER Program from the National Center for Health Statistics (NCHS) and tabulated using SEER\*Stat Version 8.2.1 (<http://www.seer.cancer.gov/seerstat/>).

Mortality data were grouped by cancer site according to the revised SEER Cause of Death Recode 1969+ (9/17/2004). The detailed information can be found on the SEER website (<http://seer.cancer.gov/codrecode/>).

## **Population Data**

The 2008-2012 New Jersey population estimates for this report were provided by the NCI's SEER Program released in January 2015 and downloaded from the SEER website (<http://www.seer.cancer.gov/popdata/download.html>). The population estimates represent a modification of the intercensal and Vintage 2013 annual time series of July 1 county population estimates by age, sex, race, and Hispanic origin produced by the US Census Bureau's Population Estimates Program, in collaboration with the National Center for Health Statistics, and with support from the NCI through an interagency agreement. The bridged single-race estimates and a description of the methodology used to develop them are available on the National Center for Health Statistics (NCHS) website ([http://www.cdc.gov/nchs/nvss/bridged\\_race.htm](http://www.cdc.gov/nchs/nvss/bridged_race.htm)).

## **Description of Algorithm for Designating Hispanic Ethnicity**

In 2003, the NJSCR adopted the NAACCR Hispanic Identification Algorithm (NHIA) to assign Hispanic ethnicity to cases. This method uses data on birthplace, marital status, gender, race and surname match to the 1990 Hispanic surname list to augment the number of cases and decedents reported as Hispanic in the registry.

Since 2005, NAACCR made several revisions to the NHIA algorithm, now NHIA version 2. The most significant change in NHIA version 2 was the two additional options for registries to apply the algorithm to counties in which the Hispanic population is less than five percent. The NJSCR applied the algorithm to all records from patients residing in all New Jersey counties (option 0 of the NHIA algorithm) diagnosed during the years 1990-2012.

As a result of applying the NHIA algorithm, the number of cases who were coded as Hispanic increased by 22 percent for this time period, thereby correcting an under-identification of Hispanics. A more complete description of the NHIA version 2 is available at the following link to the NAACCR website:

<http://www.naacr.org/LinkClick.aspx?fileticket=6E200T41TcA%3d&tabid=118&mid=458>.

For a copy of the NHIA SAS program, please see the NHAPIIA SAS Code and Related Files section on the following link to the NAACCR website:

<http://www.naacr.org/DataandPublications/CallforData.aspx>.

Caution should be used when comparing rates among Hispanics with the rates in the different race groups (e.g., black, white) because ethnicity and race are not mutually exclusive. In New Jersey, the majority of Hispanics identify themselves as white. The Hispanics who identify themselves as white, black, or API are included in the white, black, or API race category, as well as the 'all races' category.

Caution should also be used when comparing Hispanic mortality data to Hispanic incidence data in this report. Hispanic mortality data for this report were obtained from NCI's SEER Program and did not have the algorithm applied to them. In our detailed report, *Cancer Among Hispanics in New Jersey, 1990-1996*, our previous Hispanic algorithm was applied to mortality

data from the New Jersey Center for Health Statistics, resulting in an increased mortality rate of 13% for men and 23% for women.

## **Race**

Race information in the NJSCR database is collected from medical records and is not always complete and accurate. The impact of missing race for a relatively small proportion of cases results in slightly lower race-specific cancer incidence rates and counts. A small percentage of cases diagnosed in previous years were reported to the NJSCR with missing information on race at the time of the completion of last year's report, *Cancer Incidence and Mortality in New Jersey 2007-2011*, and later had their race updated after the publication of the report. This resulted in a slight increase in the race-specific cancer incidence rates and counts during 2008-2011 in the current report as compared to previous reports.

## **Asians and Pacific Islanders**

Asians and Pacific Islanders account for only 3.5% of the total cancer cases in New Jersey, and missing race or misclassification of race may have a relatively greater effect on API cancer rates than rates for other racial groups. For total cancer cases diagnosed during 2008-2012, 1.5% were reported to be of other or unknown race. The NJSCR applied the NAACCR Asian Pacific Islander Identification Algorithm version 1 (NAPIIA v1.2.1) using the birthplace and name fields (first, last, and maiden names) to classify cases directly or indirectly as Asian/Pacific Islander for analytic purposes. The NAPIIA algorithm is focused on coding cases with a race code of other Asian or other Pacific Islander to a more specific Asian or Pacific Islander race category, and the total API case count did not change after applying the algorithm.

## **Data Presentation**

### **Suppression of Rates and Counts under Five**

It should also be noted that the annual rates for relatively uncommon cancers tend to fluctuate substantially from year to year because of small numbers of cases, particularly in minority populations. Rates generated from small numbers should be interpreted with caution. For this report, incidence rates and counts were suppressed where counts were fewer than five as a way to ensure statistical reliability and patient confidentiality. The mortality data were provided through NCI's SEER program in the SEER\*Stat database and the data were suppressed by default where counts were fewer than ten.

### **Calculation of Rates**

All the counts and rates were tabulated using SEER\*Stat Version 8.2.1 (<http://www.seer.cancer.gov/seerstat/>), a statistical software package distributed by the National Cancer Institute. U.S. cancer incidence data were obtained from NAACCR's publication, *Cancer in North America 2008-2012*

(<http://www.naaccr.org/DataandPublications/CINAPubs.aspx>). All rates are age-adjusted to the 2000 U.S. Standard Population (19 age groups-Census P25-1130).

### **Rate Calculation Formulas**

A cancer incidence rate is defined as the number of new cases of cancer detected during a specified time period in a specified population. Cancer rates are most commonly expressed as cases per 100,000 population. Cancer occurs at different rates in different age groups, and population subgroups defined by gender and race have different age distributions. Therefore, before a valid comparison can be made between rates, it is necessary to standardize the rates to the age distribution of a standard population.

The first step in the age-standardization procedure is to determine the age-specific rates. For each age group for a given time interval (within each race-gender group, for the entire state), the following formula is applied:

$$r_a = \frac{n_a}{t \times P_a}$$

where

- $r_a$  = the age-specific rate for age group a,
- $n_a$  = the number of events (cancer diagnoses) in the age group during the time interval,
- $t$  = the length of the time interval (in years), and
- $P_a$  = average size of the population in the age group during the time interval (mid-year population or average of mid-year population sizes).

In order to determine the age-adjusted rate, a weighted average of the age-specific rates is calculated, using the age distribution of the standard population to derive the age-specific weighting factors (Rothman, 1986). This is the technique of direct standardization which uses the following formula:

$$R = \frac{\sum_{a=1}^n r_a \times Std. P_a}{\sum_{a=1}^n Std. P_a}$$

where

- $R$  = the age-adjusted rate,
- $r_a$  = the age-specific rate for age group a, and
- $Std.P_a$  = the size of the standard population in each age group a.

While age standardization facilitates the comparison of rates among different populations, there can be important age-specific differences in disease occurrence, which are not apparent in comparisons of the age-adjusted rates (Breslow and Day, 1987).

Analogous definitions and calculations apply for cancer mortality rates.
